Step 1 - Open the lab repo

We have prepared an application for you to extend using the techniques in the course.

git clone https://github.com/AndySmithQA/QAMDAIWCP-Lab

Open VSCode and select the QAMDAIWCP Folder

Step 2 - Understanding the code base with /explain

This is an unfamilar codebase. Start by understanding how it works.

******** Always a good plan to branch the repo locally at this point ********

You can drag the src folder into the chat window and then try /explain

Have a good read through the results. Does it make sense? Are there any obvious errors?

try this prompt:

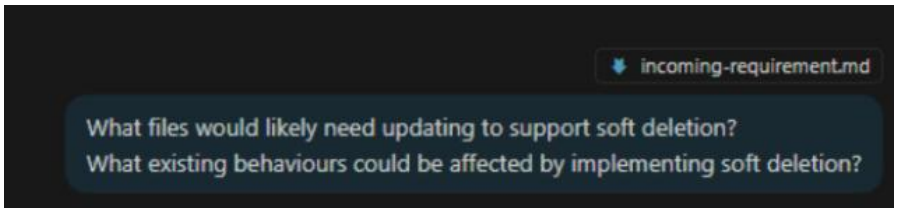

> Trace what happens when an employee is deleted.
>
> Identify the controller, service, repository and any tests involved.

Step 3 – Plan to update the functionality

Drag the incoming-requirements.md file into the chat and try a prompt like:

What files would likely need updating to support soft deletion?

What existing behaviours could be affected by implementing soft deletion?

Analyse the output.

what are the risks?

Do we need to note any interventions as the Human in control?
Change to plan mode in the chat window. Engineer a prompt like this:

Create a minimal implementation plan for the soft delete requirement.
Include:
- Files likely to change
- Purpose of each change
- Tests required
Do not include refactoring.

Once again, analyse the output. Be particularly wary of any talk of files that will need to change.

Does every proposed file support the requirement?
Is any refactoring included?
Can the scope be reduced?
Do I understand every planned change?

Pause here as there is another demonstration to come before the next lab steps. Do not close the lab!

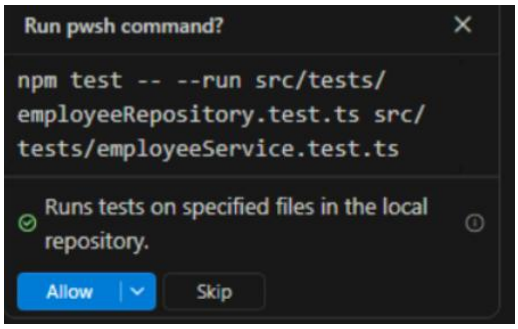

Step 4 – Stepped implementations

We are going to start the implementation now, but we want to do it a step at a time.

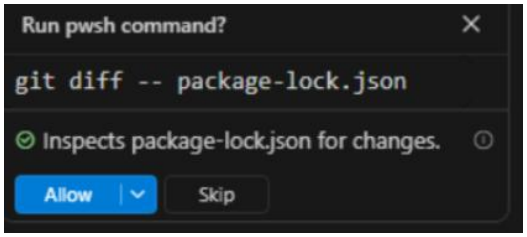

Ensure you are in Agent mode and try:

> Update the delete behaviour so employees are marked inactive instead of being permanently deleted.

if asked, allow the tests to run.

allow checks to be done on setup files if prompted

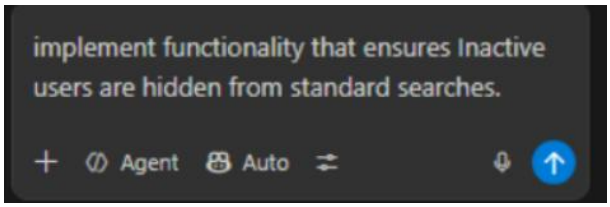

Once Copilot reports that it has finished, review the diffs

This is the most important part as you will be responsible for the code at the end of the session

Step 5 – Further Steps

Follow the same process to update the next block of functionality.

Check the diffs, allow the file changes, review the tests

Merge the branch
